

## FUNCTIONS.

Write the function of Factorial of a number.

↵

```
number = printint(input('Enter your number'))  
factorial = 1
```

```
if number == 0:
```

```
    print("Factorial is 1")
```

```
else:
```

```
    for i in range(1, number+1): // 1, 6
```

```
        factorial = factorial * i
```

```
    printf("The factorial of", number, 'is', factorial)
```

To call a function:

```
def factorial_value(num):
```

```
    factorial = 1
```

```
    if num == 0:
```

```
        return factorial
```

```
    else:
```

```
        for i in range(1, num+1):
```

```
            factorial = factorial * i
```

```
        ← return factorial
```

Numerical Python, numpy

Numpy arrays have 2 advantages over 'list' & 'tuples'.

- (i) Numpy arrays allow several mathematical operations to be performed on them in contrast to list & tuples.
- (ii) Operations on numpy is way faster compared to list & tuples.

```
np_array = np.array([1,2,3,4])  
print(np_array)
```

[1,2,3,4]

type np\_array // numpy.<sup>nd</sup>array  
1-dimensional Array

```
a = np.array([1,2,3,4])
```

a.shape // (4, 1) means 4 columns, 1 row

2-dimensional Arrays

```
b = np.array([1,2,3,4])
```

~~b = np.array([1,2,3,4])~~

```
b = np.array([1,2,3,4], [5,6,7,8])
```

```
print(b)
```

//  $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{bmatrix}$

Array of 2 rows of 4 Col.

Declaring data type in numpy arrays

Initiating Arrays

```
c = numpy np.array([1,2,3,4], [5,6,7,8], dtype=float)
```

```
x = np.zeros(4,5)
```

```
print(x)
```

//

$\begin{bmatrix} 0. & 0. & 0. & 0. & 0. \\ 0. & 0. & 0. & 0. & 0. \\ 0. & 0. & 0. & 0. & 0. \\ 0. & 0. & 0. & 0. & 0. \end{bmatrix}$

Array of <sup>ones</sup> particular value.  
~~z = np.zeros~~  
y = np.ones((3,3)) //

$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$

Array of particular value.  
z = np.full(5,4), 5)  
print(z) //

$\begin{bmatrix} 5 & 5 & 5 & 5 \\ 5 & 5 & 5 & 5 \\ 5 & 5 & 5 & 5 \\ 5 & 5 & 5 & 5 \end{bmatrix}$

Identity Matrix  
c = np.eye(3)  
print(c) //

$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

Array of Random Values:

b = np.random.random(4,4)  
print(b)

$\begin{bmatrix} 0.021 & 0.011 & 0.112 \\ 0.01 & 0.22 & 0.411 \\ 0.031 & 0.282 & 0.860 \end{bmatrix}$

Array of random int values with  
specific range &

d = np.random.randint(3,5)

d = np.random.randint(10,100,(3,5))

print(d)

$\begin{bmatrix} 11 & 59 & 68 & 54 & 87 \end{bmatrix}$

$\begin{bmatrix} 96 & 16 & 58 & 86 & 83 \end{bmatrix}$

$\begin{bmatrix} 87 & 59 & 99 & 42 & 79 \end{bmatrix}$

Lower 10, Upper 100  
(Rows, 5 col)

Array of evenly spaced values, specifying the number of values required.

```
a = np.linspace(10, 30, 6)
print(a) // [10. 14. 18. 22. 26. 30.]
```

Array of evenly spaced values, specifying the step.

```
e = np.arange(10, 30, 5)
print(e) // [10. 15. 20. 25.]
```

Converting lists to Array.

```
list_01 = [10, 20, 20, 50]
np_array = np.asarray(list_01)
print(np_array) // [10 20 20 50]
print(type(np_array)) // numpy.ndarray
```

### Analyzing an Array.

Shape of Array = c.shape

No. of Dimension of Array = c.ndim

No. of Element of Array = c.size

Check datatype of

values in the Array = c.dtype.

Mathematic Operations of an NP Array.

(+, -, \*, /) OR

```
np.add(a, b)
np.subtract(a, b)
np.multiply(a, b)
np.divide(a, b).
```

Array Manipulation.

```
array = np.random.randint(0, 10, (2, 3))
trans = np.transpose(array)
```

OR trans2 = array.T

Reshape Arrays.

```
b = a.reshape(3, 2) ... from (2, 3) shape
```

name (dataset, data, columns = dataset, feature\_names)

## Pandas

import pandas as pd

	Filename	Data Type
1.	data	<del>Nested</del> Jason
2	nestedjson	Nested Jason
3	numbertext	txt
4	text	txt
5	try	XLS.

### □ Key Syntax for Checking DataFrames

- 1) df.shape
- 2) df.head(15) // <sup>ROWS</sup> (506, <sup>COL</sup> 13)
- 3)

Exporting a DataFrame to CSV

~~df = pd.read\_~~  
df = pd.to\_csv("filename", ~~path~~)

df = pd.read\_csv(path)  
df = pd.Excel\_Excel(path)  
df = pd.read\_json(path)
